ABSTRACT: The needs for eco-friendly composites have initiated the use of agricultural wastes as possible replacements for expensive synthetic carbon and glass fillers for metal and polymer strengthening. In this study, degree of refinement of palm kernel shells, coconut shells and periwinkle shells has been investigated through ball-milling approach. Palm kernel, coconut and periwinkle shells were pulverised using disc grinder and refined using top-down approach under the same milling conditions. The particles of palm kernel, coconut and periwinkle shells obtained were analysed and their sizes were determined. Energy dispersive X-ray spectroscopic and X-ray Diffractometric analyses indicated different compositions of the examined agricultural wastes particles. Imaging sizing of the particles indicated attainment of nanoparticles when milling for 74 hours at 10 charge ratios for both carbonized and uncarbonized palm kernel, coconut and periwinkle shells. Comparison of sizes showed that uncarbonized palm kernel shell has a least grain size among other uncarbonized agricultural waste particles. Therefore, uncarbonised palm kernel shells have highest breakage tendency among others.

KEYWORDS: Degree, Refinement, Agricultural wastes, Fillers, Milling.

I. INTRODUCTION

Over the years, synthetic fillers have been the dominant material for reinforcement for both metal and polymer (Allaoui et al., 2002, Baghat and Verma, 2013, Chen et al., 2007). Extensive industrial applications have been hindered due to exorbitant manufacturing costs, limited availability, fibre damage, fibre mismatch and interfacial reactions (Das et al., 2008, Goto and Uchijo, 2005, Kok, 2005, Bobic et al., 2010). Recently, material scientists and researchers have been focusing attention on natural fillers as attractive alternative to synthetic fillers for reinforcement purposes due to low cost, availability, environmental friendliness and renewability (Mohammed et al., 2015).

Palm Kernel Shells (PKS) have been assessed as partial replacement for material reinforcement in concrete and water treatment (Falade, 1992, Okoroigwe et al., 2014). It has been characterised and reported to possess organic compounds (source of carbons and nitrogen) and minerals matter (silicates, oxides, etc) suitable for material fillers in construction and absorption industries (Festus et al., 2012, Alengaram et al., 2010). Moreover, potentials of coconut and periwinkle shells (PS) for reinforcing polymer and metals have been found in literatures.

Proper and profitable utilisation of agricultural waste will reduce the negative impacts of poor waste disposal such as air pollution caused by burning of agricultural wastes (palm kernel shells). This process leads to release of harmful gases (methane, black smoke) that could cause respiratory problem (Romulo, 2013). Using the waste could also advance the knowledge of local entrepreneurship and create job for youths through Nigerian Government Local Content Policy.

Many natural reinforcements have been used by researchers (Ibhádode and Dagwa, 2008b, Nwaobakata and Agunwamba, 2014, Ademoh and Adeyemi, 2015, Ibhádode and Dagwa, 2008a, Yawas et al., 2016) for composite development, the detailed synthesis of such fillers is very scarce though recently; (Bello et al., 2015a) studied the effects of charge ratios and milling durations on particles sizes of coconut shell nanoparticles. Similar studies on other natural fillers namely PKS and PS are scarce if found at all. In this work, attempt has been made to study and compare ball-milling breakage tendencies of three selected agricultural wastes namely PKS, PS and coconut shells (CNS).

Strengthening mechanism of particle reinforced composites depends on particle size, particle weight fraction, interfacial adhesion between the particles and matrix. Refinement of particle grains increases the particle concentration within a matrix and reduces the inter-planar spacing among particles within the matrix. Consequently, the composites packing densities increase and limit the dislocation movement within the matrix in metallic composites. Similarly, craze formation leading to shear yielding in polymeric composites is reduced due to particle refinement. Similar explanation has been found in (Lucas et al., 2011, William, 2007, Bello et al., 2017b).

II MATERIALS AND METHODS

The palm kernel, coconut and periwinkle shells used for this study were procured from the Umungbor Umuegwu Ekwerazu in Ahiazu Local Government Area of Imo State. Equipment used includes disc grinder, electric furnace, crucibles, digital weighing scale, tumbler ball mill, set of sieves with a sine shaker, Transmission Electron Microscope

*Corresponding author's e-mail address: adekunleshaafu@gmail.com

(TEM) and X-Ray Diffractometer (XRD). 5kg each of palm kernel, coconut and periwinkle shells were rinsed and dried at 6 hours per day for four weeks at 120°C using Shel lab oven to eliminate moisture and subsequently crushed into pieces at Federal Industrial Institute of Research Oshodi (FIIRO) with the aid of Broyeur Clero Hammer Crusher, model 000T (No. 13634) and pulverised into powder with the use of disc grinder. Part of agricultural waste powders obtained was sorted into different particle sizes using set of sieves (650 – 45 µm) vibrated with a sine shaker for 1 hour. The powders retained below the 45 µm sized sieve, were used as the feed powders for the synthesis of nanoparticles.

The remaining powders each of PKS, CNS and PS were placed in different known weight crucibles, sealed, reweighed and fired to 1100oC using electric furnace. This process is called carbonization. The carbonization temperature used is in line with literature (Bello *et al.*, 2017a, Bello *et al.*, 2016, Abiko *et al.*, 2010). Each of the powder samples was held at this temperature for 1 hour after which the furnace was switched off and the powders were left in the furnace to cool to room temperature. Crucibles were reweighed and the carbonized samples were graded using the same set of sieves vibrated for the same time as explained in the case of uncarbonized samples.

Samples of carbonized powders retained below 45 µm sized sieve, were selected for nanoparticle synthesis. Ball-milling of each powder sample was carried out for 74 hours at 10 charge ratios and 195 revolutions per minute (rpm) using balls of the same size ranges (5-70 mm). A tightly packed Flender Himmel electric motor powered tumbler ball mill, model A50A2043 was used. Each milled sample was analysed using XRD and TEM. Figure 1 shows the photo macrographs of agricultural wastes used in this study before and after milling.

III RESULTS AND DISCUSSION

Figures 2-7 reveal the TEM images, size distribution and elemental compositions of uncarbonized and carbonized agricultural waste particles obtained after 74 hours milling at 10 charge ratios. Fine particles of PKS are seen in Figure 2 forming globular networks of different sizes. The globules are attributed to coalescence of numerous fine particles due to milling ball impacts. Size determination using Gwyddion software indicates that size of PKS particles varies between 1.4 and 160.2 nm. Energy dispersive X-ray spectroscopic analysis reveals that PKS contains both metals and non-metals. Oxygen (O), calcium (Ca), Carbon (C) and Copper (Cu) have higher peaks while others are the minor elements.

Most of these elements represent mineral contents such as silicate, and oxides of the PKS as indicated by X-ray diffractogram in Figure 8. Carbon (C) may represent amorphous organic compounds present in the PKS as revealed by broad peaks in Figure 8. This observation is analogous to that of (Edmund *et al.*, 2014). Similarly, sizes of uncarbonised CNS and PS particles vary between 0 and 191 nm and 0 and 148 nm, respectively. CNS has C, Cu and O as major elements as indicated by EDX in Figure 3. This agrees with XRD in Figure 9 showing C8 with the highest peak. Other elements such as Cu, Si and Mg exist as silicates which are mineral components of the CNS. Bello *et al.*, (2015) reported synthesis of CNS nanoparticles through ball milling for a period range from 16 to 70 hours. Average size of their CNS nanoparticles at 70 hours is 56.03 nm.

Findings from XRD study on CNS by (Bello *et al.*, 2015a) have revealed CNS structures which are like observation in this present study. Also, sizes of PS particles fall between 0 and 148 nm. Energy dispersive X-ray spectroscopic analysis indicates Ca as a major element of PS as shown in Figure 4. This element (Ca) exists as carbonate as shown by XRD in Figure 10. A change in properties was observed after carbonization of the agricultural wastes as shown in Figures 5-7. Image of carbonized PKS particles in Figure 5 appears more fused together than what is observed in Figure 2 of uncarbonized PKS particles. Sizes of carbonised PKS particles fall between 0 and 160 nm.

Carbon peak in Figure 5 is much higher than that in Figure 2. This can be attributed to distillation of the volatile components which has led to an increase in C counts. An increase in C content is compensated by reduction in the counts of the elements such as O. Similar observation was made in case of carbonized CNS and PS particles. This finding is in line with literature (Adebisi *et al.*, 2017b, Bello *et al.*, 2106, Bello *et al.*, 2015a, Bello *et al.*, 2015b).

Moreover, XRD peaks in Figure 8 show Mg_2O_4Si , $Al_{2.7}CaCu_{0.83}$, $Al_{10.56}Mg_{0.44}$. These compounds represent mineral components of PKS and agree with findings from XRD in Figure 2. Presence of intermetallic compounds including $Al_{2.7}CaCu_{0.83}$, $Al_{10.56}Mg_{0.44}$ is attributed to unavoidable chemical reaction between phases of uncarbonised PKS during ball milling process. Similar chemical reaction was disclosed in literature during refinement of CNS through ball-milling process (Bello *et al.*,

2015a, Bello et al., 2015b). Such chemical reaction is called mechanical alloying as found in literature (Chauruka et al., 2015, Maurice and Courtney, 1990, Qu et al., 2015). Similarly, SiO₂, Cu₄MgO₅, Cu₁₆O_{14.5} are observed with XRD peaks of uncarbonised CNS nanoparticles in Figure 9. These compounds affirm silica contents of CNS.

Presence of silica in organic wastes such as CNS, rice husk, cassava periderm and others has extensively been reported in literature (Romulo, 2013, Adebisi et al., 2017a, Adebisi et al., 2017b). Intermetallic Cu₄MgO₅ and Cu₁₆O_{14.5} are attributable to unavoidable chemical reaction due to extremely high surface energy during particle refinement (Moreno and Ferrari, 2012, Pokropivny et al., 2007). Moreover, all peaks in Figure 9 indicate CaCO₃. This finding agrees with earlier studies showing that snail, periwinkle and egg shells contain at least 85 % CaCO₃. Remaining percentage may account for boron and nitrogen compounds (Agunsoye et al., 2015a, Agunsoye et al., 2015b, Agunsoye et al., 2016).

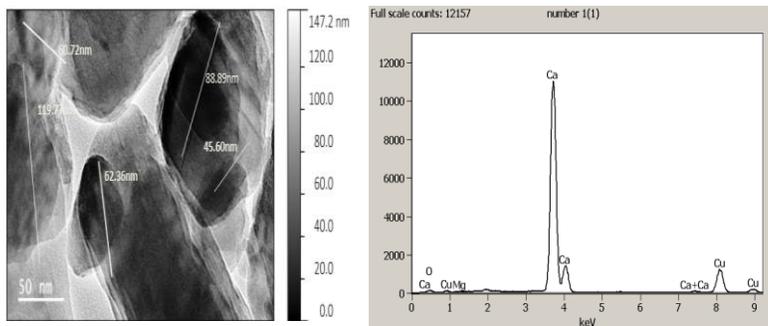

Figure 4: TEM/Gwyddion image showing size distribution/EDX of uncarbonized periwinkle shells nanoparticles process.

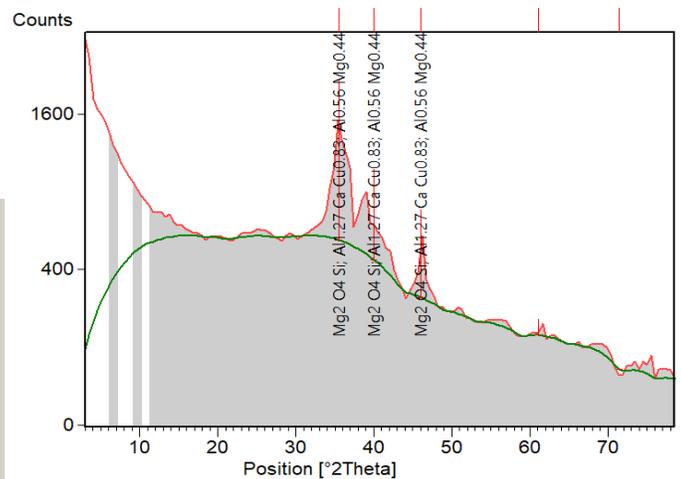

Figure 8: X-ray diffractogram of uncarbonized PKS nanoparticles.

However, PKS has the least particle size indicating highest refinement abilities among other agricultural wastes used in this study. Excellent refinement property of PKS can be linked to presence of hard or brittle components of the PKS. After carbonization, refinement properties of all agricultural wastes increased. It is indicated by smaller sizes of carbonised agricultural waste particles than uncarbonised ones as shown in Figure 13. In this case, carbonised periwinkle shell particles (CPS) have least particle sizes. This observation is linked with phases of PS that are mainly CaCO_3 which decomposes to brittle CaO while heating above 660°C in line with literature (Hunton, 2005).

IV SUMMARY AND CONCLUSIONS

Carbonized and uncarbonized nanoparticles of palm kernel, coconut and periwinkle shells have been synthesised from precursor powder of $45\ \mu\text{m}$ through continuous ball-milling for 74 hours at 10 charge ratios. Size determination indicated minimum size of $56.53\ \text{nm}$ belonging to uncarbonized palm kernel shell among other uncarbonized agricultural wastes and $49.23\ \text{nm}$ for carbonized periwinkle shells. Highest degree of refinement confirmed with carbonized periwinkle shell particles is linked to brittleness of CaO that may result from decomposition of CaCO_3 during carbonization of periwinkle shells. Therefore, syntheses of palm kernel and periwinkle shells nanoparticles have been obtained and its effects on mechanical properties of aluminium metal matrix composites will be communicated in another article in future.

V ACKNOWLEDGEMENTS

Authors express their appreciation to Department of Metallurgical and Materials Engineering, University of Lagos; Ceramics Department, Federal Industrial Institute of Research Oshodi and Dr Victor Aigbodion, Department of Metallurgical and Materials Engineering, Nigeria University, Nsukka for their assistance in making this work successful.
